Chapter 8: Modern Recurrent Neural Networks

Mina Rezaei

Department of Statistics – LMU Munich Winter Semester 2020

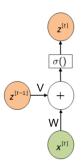

LECTURE OUTLINE

Long Short-Term Memory (LSTM)

Gated Recurrent Units (GRU)

Long Short-Term Memory (LSTM)

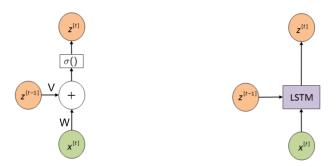

The LSTM provides a way of dealing with vanishing gradients and modelling long-term dependencies.

Until now, we simply computed

$$\mathbf{z}^{[t]} = \sigma(\mathbf{b} + \mathbf{V}^{\top} \mathbf{z}^{[t-1]} + \mathbf{W}^{\top} \mathbf{x}^{[t]})$$

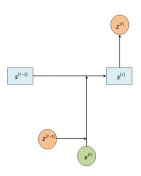

The LSTM provides a way of dealing with vanishing gradients and modelling long-term dependencies.

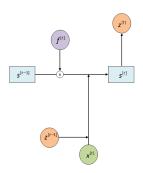

Until now, we simply computed

$$\mathbf{z}^{[t]} = \sigma(\mathbf{b} + \mathbf{V}^{\top} \mathbf{z}^{[t-1]} + \mathbf{W}^{\top} \mathbf{x}^{[t]})$$

 Now we introduce the LSTM cell (which is a small network on its own).

- The key to LSTMs is the **cell state** $s^{[t]}$.
- $\mathbf{s}^{[t]}$ can be manipulated by different **gates** to forget old information, add new information, and read information out of it.
- Each gate is a vector of the same size as the $\mathbf{s}^{[t]}$ with elements between 0 ("let nothing pass") and 1 ("let everything pass").

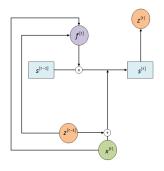

- Forget gate $f^{[t]}$: indicates which information of the old cell state we should forget.
- Intuition: Think of a model trying to predict the next word based on all the previous ones. The cell state might include the gender of the present subject, so that the correct pronouns can be used.
 When we now see a new subject, we want to forget the gender of the old one.

We obtain the forget gate by computing

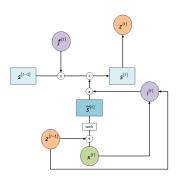

$$\mathbf{f}^{[t]} = \sigma(\mathbf{b}_f + \mathbf{V}_f^{\top} \mathbf{z}^{[t-1]} + \mathbf{W}_f^{\top} \mathbf{x}^{[t]})$$

• $\sigma()$ is a sigmoid, squashing the values to [0, 1], and V_f , W_f are forget gate specific weights.

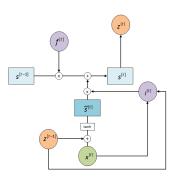

• To compute the cell state $\mathbf{s}^{[t]}$, the first step is to multiply (element-wise) the previous cell state $\mathbf{s}^{[t-1]}$ by the forget gate $\mathbf{f}^{[t]}$.

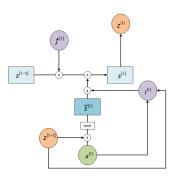

$$extbf{ extit{f}}^{[t]}\odot extbf{ extit{s}}^{[t-1]}, ext{ with } extbf{ extit{f}}^{[t]}\in[0,1]$$

- Input gate i^[t]: indicates which new information should be added to s^[t].
- Intuition: In our example, this is where we add the new information about the gender of the new subject.

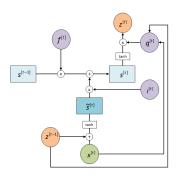

- The new information is given by $\tilde{\mathbf{s}}^{[t]} = \tanh(\mathbf{b} + \mathbf{V}^{\top} \mathbf{z}^{[t-1]} + \mathbf{W}^{\top} \mathbf{x}^{[t]}) \in [-1, 1].$
- The input gate is given by $\mathbf{i}^{[t]} = \sigma(\mathbf{b}_i + \mathbf{V}_i^{\top} \mathbf{z}^{[t-1]} + \mathbf{W}_i^{\top} \mathbf{x}^{[t]}) \in [0, 1].$
- W and V are weights of the new information, W_i and V_i the weights of the input gate.

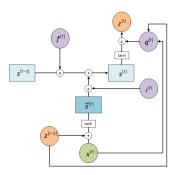

• Now we can finally compute the cell state $\mathbf{s}^{[t]}$:

$$\mathbf{s}^{[t]} = \mathbf{f}^{[t]} \odot \mathbf{s}^{[t-1]} + \mathbf{i}^{[t]} \odot \mathbf{\tilde{s}}^{[t]}$$

- Output gate $q^{[t]}$: Indicates which information form the cell state is filtered.
- It is given by $\mathbf{q}^{[t]} = \sigma(\mathbf{b}_q + \mathbf{V}_q^{\top} \mathbf{z}^{[t-1]} + \mathbf{W}_q^{\top} \mathbf{y}^{[t]})$, with specific weights \mathbf{W}_q , \mathbf{V}_q .

 Finally, the new state z^[t] of the LSTM is a function of the cell state, multiplied by the output gate:

$$extbf{\emph{z}}^{[t]} = extbf{\emph{q}}^{[t]} \odot anh(extbf{\emph{s}}^{[t]})$$

Gated Recurrent Units (GRU)

GATED RECURRENT UNITS (GRU)

- The key distinction between regular RNNs and GRUs is that the latter support gating of the hidden state.
- Here, we have dedicated mechanisms for when a hidden state should be updated and also when it should be reset.
- These mechanisms are learned and they address the listed concerns:
 - avoid the vanishing/exploding gradient problem which comes with a standard recurrent neural network.
 - GRUâĂŹs are able to solve the vanishing gradient problem by using an update gate and a reset gate.
 - the update gate controls information that flows into memory, and the reset gate controls the information that flows out of memory.

RESET GATES AND UPDATE GATES

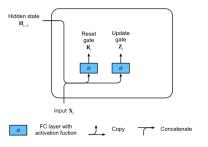

Figure: Reset and update gate in a GRU.

• as shown by Figure 1, given the current time step input X_t and the hidden state of the previous time step H_{t-1} . The output is given by a fully connected layer with a sigmoid as its activation function.

RESET GATES AND UPDATE GATES

- For a given time step t, the minibatch input is $\mathbf{X}_t \in \mathbb{R}^{n \times d}$ (number of examples:n, number of inputs:d) and the hidden state of the last time step is $\mathbf{H}_{t-1} \in \mathbb{R}^{n \times h}$ (number of hidden states:h). Then, the reset gate $\mathbf{R}_t \in \mathbb{R}^{n \times h}$ and update gate $\mathbf{Z}_t \in \mathbb{R}^{n \times h}$ are computed as follows:
- $\bullet \ \mathbf{R}_t = \sigma(\mathbf{X}_t \mathbf{W}_{xr} + \mathbf{H}_{t-1} \mathbf{W}_{hr} + \mathbf{b}_r)$
- $\bullet \ \mathbf{Z}_t = \sigma(\mathbf{X}_t \mathbf{W}_{xz} + \mathbf{H}_{t-1} \mathbf{W}_{hz} + \mathbf{b}_z)$
- Here, \mathbf{W}_{xr} , $\mathbf{W}_{xz} \in \mathbb{R}^{d \times h}$ and \mathbf{W}_{hr} , $\mathbf{W}_{hz} \in \mathbb{R}^{h \times h}$ are weight parameters and \mathbf{b}_r , $\mathbf{b}_z \in \mathbb{R}^{1 \times h}$ are biases. We use a sigmoid function to transform input values to the interval (0,1).

RESET GATES IN ACTION

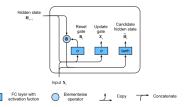

Figure: Candidate hidden state computation in a GRU. The multiplication is carried out elementwise.

- We begin by integrating the reset gate with a regular latent state updating mechanism. In a conventional RNN, we would have an hidden state update of the form:
- $\bullet \ \mathbf{H}_t = \tanh(\mathbf{X}_t \mathbf{W}_{xh} + \mathbf{H}_{t-1} \mathbf{W}_{hh} + \mathbf{b}_h).$
- $\bullet \ \tilde{\mathbf{H}}_t = \tanh(\mathbf{X}_t \mathbf{W}_{xh} + (\mathbf{R}_t \odot \mathbf{H}_{t-1}) \mathbf{W}_{hh} + \mathbf{b}_h).$

RESET GATES IN ACTION

• Figure 2 illustrates the computational flow after applying the reset gate.

UPDATE GATES IN ACTION

- aa
- Next we need to incorporate the effect of the update gate Z_t .
- The gating variable Z_t can be used for this purpose, simply by taking elementwise convex combinations between both candidates.
- This leads to the final update equation for the GRU.
- $\bullet \ \mathbf{H}_t = \mathbf{Z}_t \odot \mathbf{H}_{t-1} + (1 \mathbf{Z}_t) \odot \tilde{\mathbf{H}}_t.$

UPDATE GATES IN ACTION

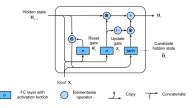

Figure: Hidden state computation in a GRU. As before, the multiplication is carried out elementwise.

These designs can help us cope with the vanishing gradient problem in RNNs and better capture dependencies for time series with large time step distances. In summary, GRUs have the following two distinguishing features:

- Reset gates help capture short-term dependencies in time series.
- Update gates help capture long-term dependencies in time series.
